Result Summary:

Based on the table, we can see that the number of producers always greater than or equal to a number of consumers. In order for a consumer to consume an item in the buffer, the buffer must be not empty. And in order for a producer to produce an item and send it to the buffer, the buffer must be not full. Therefore, for all the test cases, the consumer tends to wait until producer produces the item to the buffer, then it starts to consume the item when the buffer has item. The producer stops producing any more items to the buffer when the buffer is full, and wait till the consumer to consume the item, which frees up space for the buffer again.

Overall, the longer the sleeping time, the more items will be produced and consumed. If the sleeping time maintains at a constant, and there are a lot more consumers than producers, the consumers must wait for a long time for an item. This works vice versa for the producer. Therefore, only increasing number of producers or consumers, and not caring about the others, does not help the system process. The difference between the number of producers and consumers should be kept as small as possible.
